1. **Compute Services**

- **Azure Virtual Machines:**

Azure Virtual Machines (VMs) provide scalable computing resources in the cloud. These VMs can run Windows, Linux, or other OS and can be configured to meet specific application requirements. They offer flexibility, as they can be customized with different sizes and configurations, and support high availability and disaster recovery options. Azure VMs are suitable for a wide range of applications, from simple development and testing environments to complex, multi-tier applications.

2. **Storage Services**

- **Azure Blob Storage:**

Azure Blob Storage is a service designed to store large amounts of unstructured data, such as text or binary data. It's highly scalable and can manage large volumes of data for various uses like serving images or documents directly to a browser, streaming media, or storing backups and logs. Blob Storage supports different tiers for hot, cool, and archive storage, which help in optimizing costs based on access frequency.

3. **Database Services**

- **Azure SQL Database:**

Azure SQL Database is a fully managed relational database service based on Microsoft SQL Server. It provides built-in high availability, automated backups, and scalability options. It supports various deployment options such as single databases, elastic pools, and managed instances, making it suitable for a wide range of applications from small projects to enterprise-level applications.

- **Azure Cosmos DB:**

Azure Cosmos DB is a globally distributed, multi-model database service. It supports various data models such as document, key-value, graph, and column-family, and provides automatic and instant scalability with multi-region replication. It offers low latency, high availability, and comprehensive SLAs, making it ideal for applications that require quick response times and large-scale data handling.

4. **Networking Services**

- **Azure Virtual Network:**

Azure Virtual Network (VNet) is a service that enables secure communication between Azure resources such as VMs, databases, and applications. It provides features like subnets, routing,

network security groups, and virtual network peering, allowing the creation of complex and secure network architectures that can extend to on-premises environments.

- **Azure ExpressRoute**:

Azure ExpressRoute provides a dedicated, private connection between an organization's on-premises network and Azure data centers. This connection offers higher security, more reliability, and consistent latency compared to typical internet-based connections. It is suitable for scenarios where secure and high-performance connections are required, such as data migration, disaster recovery, and hybrid cloud applications.

5. **Serverless Compute Services**

- **Azure Functions**:

Azure Functions is a serverless compute service that allows you to run event-driven code without managing infrastructure. It supports various programming languages and can be triggered by HTTP requests, queues, timers, and more. Azure Functions is ideal for small pieces of code that need to run in response to specific events or on a schedule.

- **Azure Logic Apps**:

Azure Logic Apps is a cloud service that automates workflows and integrates apps, data, and services. It enables the creation of complex workflows with a visual designer and can connect to hundreds of services like Office 365, Salesforce, and SQL Server. It's useful for automating business processes and integrating systems without the need for custom code.

6. **Container Services**

- **Azure Kubernetes Service (AKS)**:

Azure Kubernetes Service (AKS) is a managed Kubernetes service that simplifies the deployment, management, and operations of Kubernetes clusters. It integrates with Azure services like Azure Active Directory and Azure DevOps, and supports advanced features like scaling, monitoring, and automated updates. AKS helps in running containerized applications at scale while offloading the operational complexity.

7. **Identity and Access Management**

- **Azure Active Directory (Azure AD) **:

Azure Active Directory is a comprehensive identity and access management service that provides authentication and authorization capabilities for users and applications. It supports single sign-on (SSO), multifactor authentication, and conditional access policies. Azure AD

integrates with thousands of SaaS applications and offers seamless identity management for employees, partners, and customers across cloud and on-premises environments.

8. **Monitoring and Logging**

- **Azure Monitor:**

Azure Monitor is a service that collects, analyzes, and acts on telemetry data from Azure and on-premises environments. It provides full-stack monitoring with insights across applications, infrastructure, and network. Azure Monitor helps in identifying and diagnosing issues, tracking performance, and maintaining the health and availability of applications.

- **Azure Log Analytics:**

Azure Log Analytics is a feature of Azure Monitor that collects and analyzes log data from various sources like Azure resources, applications, and on-premises environments. It uses a powerful query language to provide insights and generate alerts. It is used for troubleshooting, monitoring, and optimizing system performance.

9. **AI and Machine Learning Services**

- **Azure Machine Learning:**

Azure Machine Learning is a service for building, training, and deploying machine learning models. It supports both code-first experiences for data scientists and no-code experiences for business analysts. Azure ML provides tools for managing the entire machine learning lifecycle, including model training, deployment, and monitoring.

- **Azure Cognitive Services:**

Azure Cognitive Services offer a suite of AI services and APIs that allow developers to add intelligent features like vision, speech, language, and decision-making to their applications. These services include capabilities like image recognition, speech-to-text, sentiment analysis, and anomaly detection, enabling the integration of sophisticated AI functionality with minimal effort.

10. **Development and Deployment Tools**

- **Azure DevOps:**

Azure DevOps provides a suite of development tools for software development and deployment. It includes features for source control, continuous integration and delivery (CI/CD), agile project management, and automated testing. Azure DevOps supports collaboration and streamlined workflows for DevOps practices, enabling faster and more reliable software delivery.

- **Azure Pipelines**:

Azure Pipelines is a service within Azure DevOps that provides CI/CD capabilities for building, testing, and deploying code to any platform or cloud. It supports multiple languages and platforms and integrates with a wide range of tools and services. Azure Pipelines help automate the process of delivering software, from code commit to production deployment, ensuring quick and consistent releases.

These services reflect Azure's robust and versatile cloud platform, offering a comprehensive range of tools and capabilities for modern cloud computing needs.
